ABSTRACT

Documentation of a computer program for performing design feasibility studies of planing hulls is presented. The mathematical model is oriented to combatant craft but may also be applied to other types of planing ships with full-load displacement up to 1500 tons and speed-displacement coefficient $F_{n\nabla}$ up to 4. Options are available for structural materials of aluminum or steel or glass reinforced plastic, diesel or gas turbine prime movers with or without auxiliary engines of either type, and propellers on inclined shaftsor waterjet pumps. Weight, volume, and vertical center of gravity for the major ship components, including loads, are estimated. Hull size may either be fixed or optimized to meet design payload requirements.

ADMINISTRATIVE INFORMATION

Modifications for the current program were authorized and funded by the Naval Sea Systems Command, Detachment Norfolk (NAVSEADET Norfolk)

Project Order 00016. The work was performed at the David W. Taylor Naval Ship Research and Development Center (DTNSRDC) under Work Unit 1-1524-718.

INTRODUCTION

A computer program labeled PHFMOPT has been developed at DTNSRDC and utilized in numerous design feasibility studies by NAVSEADET Norfolk for combatant craft projects such as the Special Warfare Craft, Medium SWCM and Landing Craft LCM-9. The computer software has been revised and updated numerous times to keep abreast of the project requirements and state-of-the-art. This report provides a general description of the present mathematical model together with documentation for each module of the computer program in Appendix A. This program is operable on the Control Data Corporation 6000 Computers at DTNSRDC and has also been recently installed on the Digital Equipment Corporation PDP/8 Computer at NAVSEADET Norfolk. Sample input and output are shown in Appendix B.

The planing hull feasibility model PHFMOPT is applicable for a wide range of planing-hull prototypes with slenderness ratio $\mathrm{Lp/V}^{1/3}$ from 4 to 10, speed-displacement coefficient $\mathrm{F_{nV}}$ from 0.5 to 4.0, and displacement from 50 to 1500 tons. A comparison of the model with an actual patrol craft and an example of a design study utilizing the model has been presented in Reference 1.

^{*} A complete listing of references is given on page 17.

GENERAL DESCRIPTION OF MODEL

Computer program PHFMOPT estimates the weight, volume, and vertical center of gravity VCG of major components for the empty ship plus the fuel load, crew, and provisions. Then, either (1) the resultant weight, volume, and VCG of the payload is computed for a hull of fixed size, or (2) the hull depth H_h , maximum chine beam B_{pX} , and/or displacement Δ_{LT} are optimized to meet design payload requirements for a ship of fixed length L_p . Computations may be made for several values of L_p to determine the optimum ship length.

Ship components for the U.S. Navy Bureau of Ships Consolidated Index BSCI Groups 1 through 6 are computed at the three-digit level. The data base for the model includes small patrol craft, hydrofoil craft, destroyers DD, and destroyer escorts DE so that planing ships up to 1500 tons can be evaluated. A multiplier (K-factor) is input for each three-digit BSCI group which may be used to modify or eliminate weights and volumes derived from the general equations presented in Appendix A. A K-factor is also applied to the total of each single-digit group, essentially adding a designer's margin.

Input to the program is read by Subroutine READIN and consists of 54 punched data cards which contain offsets for the parent hull form and design constants. Data from the cards are immediately printed for use in checking input errors. In addition, one card for each design condition, containing the length L_p and initial values of Δ_{LT} , B_{pX} , and H_h , is read by the executive routine PHFMOPT. A detailed description of the input and the printed output is presented in Appendix A. Output is controlled by Subroutine PRTOUT.

HULL GEOMETRY

The planing hull is represented by a hard-chine model as shown in Figure 1. Offsets input for the parent hull form are nondimensionalized in Subroutine PARENT. Offsets and hydrostatics for each new design condition of L_p , $B_{p\chi}$, and Δ_{LT} are computed by Subroutine NEWHUL. All parametric variations have the same deadrise as the parent, since the keel and chine offsets are proportioned by the average beam B_{PA} and $B_{P\chi}/B_{PA}$ is held constant. The hull volume below the main deck ∇_h and the hull density

 Δ/∇_h are computed by Subroutine NEWVOL for each change in H_h . Slope of the hull sides is maintained whenever deck height is changed.

The general arrangement of the transverse bulkheads, platforms, and fuel tanks employed by the planing hull model is shown in Figure 2. Nine bulkheads positioned as shown are used for planing hulls over 70 tons and should be sufficient for a two-compartment ship aft and a three-compartment ship forward for most configurations. The number of bulkheads is reduced for smaller craft based on existing designs. The general arrangement used for the landing craft model is shown in Figure 3. For this special case, additional input parameters are required to define the well deck and ramps. A maximum of 15 bulkheads may be input, and a spacing of about 6 ft between bulkheads is used under the well deck.

STRUCTURES

The hull structures (BSCI Group 1) are computed in Subroutine STRUCT. The structural design procedure takes into account sea loads and effects of changes in hull length, beam, and depth. The design methodology is based on References 2, 3, and 4 and explained in detail in Reference 1. Structures of either aluminum, steel, or glass reinforced plastic GRP may be computed. Two interchangeable Subroutines STRUCT are available, one for aluminum or steel hulls, the other for single skin or sandwich plate GRP hulls. Curves of structural weight data used by the math model are shown in Figures 4, 5, 6, 7, and 8.

A third Subroutine STRUCT is available for landing craft of aluminum or steel which accounts for the increased load on the well deck and ramps and changes in the internal arrangement.

RESISTANCE

Bare-hull resistance for the feasibility model is estimated from DTNSRDC Series 62 and 65 hard-chine planing hull data published in Reference 5. Mean values of resistance/weight ratio R/W as a function of $L_p/\nabla^{1/3}$ and $F_{n\nabla}$ were computed from the 21 models of the two series with the longitudinal center of gravity LCG position ranging from 1/3 to 1/2 L_p forward of the transom. Mean values of wetted area coefficient $S/\nabla^{2/3}$ were obtained for the same data. Faired curves of the mean R/W for a

100,000-1b planing craft and mean $S/\nabla^{2/3}$ are presented in Figures 9 and 10. Data from the faired curves have been incorporated in Subroutine PHRES (see Tables 1 and 2) so that the mean R/W can be interpolated for $L_p/\nabla^{1/3}$ from 4 to 10 at $F_{n\nabla}$ from 0 to 4 and scaled to the required ship size. Standard deviation σ of the base data from the mean values was also computed and faired as a function of $F_{n\nabla}$. A multiplier SDF may be used with σ to raise or lower the mean R/W data when attempting to match existing resistance data for a particular hull form.

Predicted R/W = Mean R/W - (SDF x
$$\sigma$$
)

Resistance of the appendaged hull is estimated by applying an appendage drag factor $\boldsymbol{\eta}_a$ to the bare-hull resistance. The factor $\boldsymbol{\eta}_a$ developed by Blount and Fox, Reference 6, is applied only to hulls with propellers on inclined shafts. No increase in resistance is assumed for hulls fitted with waterjets.

Added resistance in rough water R_{aw} is predicted from an empirical equation given in Reference 7 which was developed by a regression of planing hull rough-water experimental data.

$$R_{aw}/\Delta = 1.3 (H_{1/3}/B_{PX})^{0.5} F_{n\nabla} (L_{P}/\nabla^{1/3})^{-2.5}$$

THRUST

The feasibility model has the option for either propellers on inclined shafts or waterjet pumps. Thrust deduction (1-t) used for the propellers is 0.92 from Blount and Fox, Reference 6. Thrust deduction assumed for waterjets is 0.95. Total thrust requirement $T = R_t/(1-t)$ where R_t is total resistance.

Subroutine PROPS is utilized to estimate the powering requirements for the ship at design and cruise speed when propellers are employed. If not input, the number of propellers is selected based on maximum power of prime movers available. Subroutine PROPS also determines propeller diameter if not specified, selecting the smallest propeller capable of producing the required thrust at both design and cruise speeds, based on an input constant for $\tau_{\rm c}/\sigma_{0.7R}$. A value of $\tau_{\rm c}/\sigma_{0.7R}$ $^{\sim}$ 0.6 corresponds to the 10 percent back cavitation criteria for Gawn-Burrill type propellers.

Propeller open-water characteristics are derived as a function of pitch ratio P/D, expanded area ratio EAR, and number of blades Z from polynomials developed from the Wageningen B-Screw Series of airfoil section propellers, Reference 8, or recent modifications of these polynomials for flat face, segmental section propellers such as the Gawn-Burrill Series, Reference 9. Propeller characteristics in the cavitation regime are derived from maximum thrust and torque load coefficient $\tau_{\rm c}$ and $\tau_{\rm c}$ developed as functions of cavitation numbers at the propeller 0.7 radius $\tau_{\rm c}$ in Reference 10.

Subroutine WJETS is used to estimate the power requirements with waterjet pumps. Waterjets of fixed size may be input, or the waterjets may be designed within the program using the approach given by Denny in Reference 11. The design pumps are assumed to operate at maximum input power and maximum rpm at the ship's design speed. A ratio of bollard jet velocity V_{JB} to ship speed V_{S} about 2 will result in optimum propulsive efficiency; see Figure 3 of Reference 11. However at low design speeds, e.g., 20 knots, a value of $V_{JB}/V_{S} > 2$ may be required in order to keep the size of the waterjet within reasonable bounds.

PROPULSION

Once the power estimates are made for design and cruise speeds, the propulsion (BSCI Group 2) components are calculated in Subroutine POWER. The following propulsion systems are available in the computer model:

- (1) diesel prime movers,
- (2) gas turbine prime movers,
- (3) CODOG system -- gas turbine prime movers with auxiliary diesels,
- (4) COGOG system -- gas turbine prime movers with auxiliary gas turbines.

There is always one prime mover for each propeller or waterjet. The prime movers are designed to operate at maximum power at the ship's design speed; the auxiliary engines operate at their maximum power at cruise speed.

General equations for specific weight, rotational speed, and specific fuel consumption SFC have been developed for high speed diesels and second generation gas turbines. Data from the general equations may be modified by input constants to match a particular series of engines, or fixed weights and SFC's may be input to the program. Gear weights may be fixed or derived from a general equation developed by Mandel at Massachusetts Institute of Technology with appropriate constants for either single reduction or planetary gears. Propeller and waterjet weights are primarily a function of their size. Subsidiary propulsion system weights are given as a function of the total power of the prime movers.

Volumes required for the engine room, combustion air supply, and uptakes may be fixed inputs or obtained from the general equations based on existing diesel and gas turbine systems.

OTHER SYSTEMS

The electric plant (BSCI Group 3) components are computed in Subroutine ELECPL. The electric power requirement in kilowatts may be an input or computed as a function of the ship displacement.

The nonelectronic navigation equipment and interior communication system are established in Subroutine COMCON. The remainder of communication and control (BSCI Group 4) is considered part of the payload.

Auxiliary systems (BSCI Group 5) and the outfit and furnishings (BSCI Group 6) are computed in Subroutines AUXIL and OUTFIT. The general equations were primarily derived from DD and DE data. However, changes were made for aluminum components in lieu of steel, using 2/3 the weight of steel where equal stress is required and 1/2 the weight of steel where size is maintained.

LOADS

The fuel requirement is established in Subroutine POWER based on the SFC and range at either cruise speed or design speed, whichever dominates. A five percent margin is added for fuel which cannot be utilized. An additional five percent margin is added to the volume of the fuel tanks

to allow for expansion. The fuel tanks are generally an integral part of the hull structure, but an option is available for separate fuel tanks when required.

The ship's complement may either be input or calculated in Subroutine CREWSS based on accommodations of numerous small and intermediate-sized warships. The crew concerned with the military payload is included in the total complement and not treated as part of the military payload. Weights and volumes of the crew and their effects based on U.S. Navy standard allowances, as well as personnel stores and potable water for the specified accommodations and days at sea, are computed in Subroutine LOADS.

The components of BSCI Groups 1 through 6 are combined and specified margins added in Subroutine TOTALS to obtain the empty ship weight, volume, and VCG. The difference between the full-load displacement and the empty ship weight is termed the useful load, which includes the fuel, crew and provisions, and the payload. The payload consists of the armament (BSCI Group 7), the military portion of communication and control (Group 4), ammunition, and any special loads required for the ship's mission, such as the tanks carried by a landing craft. The computer model does not separate the various components of the payload.

OPTIMIZATION

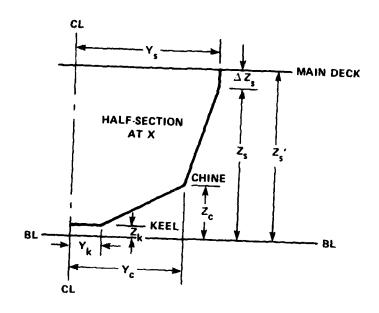

Unless the hull size is fixed, the executive routine PHFMOPT iterates until the design payload specifications are met, or until a default condition occurs. The ship displacement is increased or decreased until the resultant payload weight W_p is equal to the input value for design payload. The beam of the hull is varied until the specified VCG of the design payload is obtained, maintaining the input metacentric height $\overline{\text{CM}}$. The hull depth is raised or lowered to obtain the design payload volume ∇_p (payload density = W_p/∇_p). A flow chart of the optimization process is presented in Appendix A.

Possible default conditions are as follows:

- (1) $L_p/\nabla^{1/3}$ less than 4 or greater than 10,
- (2) $F_{n\nabla}$ greater than 4,
- (3) Δ_{LT} , B_{PX} , or H_h not converging after 10 iterations for each variable. A default may occur if the initial values of Δ_{LT} , B_{PX} , and H_h are not close to the optimums. Therefore, the program user may be wise to begin a new design with several fixed hull sizes to aid in the selection of initial values for the optimization process.

FINAL HULL

Weights, VCG's, and volumes for the final (or fixed) hull form are printed from Subroutine PRTOUT at the BSCI 3-digit level. Also output are offsets and hydrostatics for the final hull, speed-power predictions for a range of speeds, and some vertical acceleration predictions in various sea states based on empirical equations in Reference 12. A sample printout is shown in Appendix B.

PROGRAM PHFMOPT

	TROUBLE THEOLET
HD(I)	H _h = hull depth at midships of current hull
	If NVD = 1, then $H_h = H_h$ or H_{min} or H_{max}
	If NVD = 3, then $H_h = H_h + dH_h$, H_h , $H_h - dH_h$
PDEN(I)	W_p/V_p = payload density of current hull
ZPL(J)	Z _p = VCG of payload for current hull
WPD(L)	W _p = weight of payload for current hull
HDM	H _h = final hull depth in ft
	If NVD = 3, interpolate from the array of W_p/∇_p
	versus H_h to obtain a new H_h which approximates
	the required $(W_p/\nabla_p)_D$. Iterate until the new
	H_{h_0} agrees with the old H_{h_0} within one percent.
PDENS	W_p/∇_p = payload density of final hull
BPX	B_{PX} = final maximum chine beam in ft
	If NBX = 3, interpolate from the array of Z_p versus
	$B_{\rm PX}$ to obtain a new $B_{\rm PX}$ which approximates the
	required $(Z_p)_D$. Iterate until the new B_{pX} agrees
	with the old B_{PX} within one percent.
DTONS	$\Lambda_{ m LT}$ = final displacement in tons
	If NDT = 3, interpolate from the array of W_{p}
	versus $\boldsymbol{\Delta}_{LT}$ to obtain a new $\boldsymbol{\Delta}_{LT}$ which approximates
	the required $(W_p)_D$. Iterate until the new Δ_{LT}
	agrees with the old $\Delta_{ ext{LT}}$ within one percent. $^{ ext{O}}$
	A maximum of 10 iterations is set on each loop.
	If the initial values of $\Delta_{\mathrm{LT}_{\mathrm{O}}}$, $B_{\mathrm{PX}_{\mathrm{O}}}$, and/or $H_{\mathrm{h}_{\mathrm{O}}}$
	are too far from the design requirements, convergence may be unattainable with this optimization procedure. Therefore, it is well to run a matrix of fixed hulls (IOPT=0) first to aid in the selection of appropriate initial values.
	See Subroutine PRTOUT for complete output from final hull.

NAME:	SUBROUTINE	READIN

PURPOSE: Read input data from punched cards, and echo the

input. Store data in COMMON blocks for use by other

routines.

	YK (I)	Half-breadth at keel Y _K		49-56
		45		

Format for Card 1 is (5 A 10).

Format for Cards 3, 4, and 6 is (20 I 4).

Format for all other cards is (10 F 8.2).

Data read from each card is immediately echoed, i.e., printed on output page, for use in tracing errors.

Card Columns

Card Set 5 contains NN cards, one for each section, in order from transom to bow.

For conventional planing hulls, value of NN must be 27 and sections required are $\rm X/L_p=0$, 0.025, 0.05,

0.075, 0.1, 0.15, 0.2, 0.25, 0.3, 0.35, 0.4, 0.45, 0.5, 0.55, 0.6, 0.65, 0.7, 0.75, 0.8, 0.85, 0.875, 0.9, 0.925, 0.95, 0.975, 1.0, and L_{OA}/L_{P}

Values of N, M, M40, M25 are 26, 13, 15, 18. Sections for landing craft are not restricted.

Dimensions of offsets on Card Set 5 must be consistent with values on Card 2. The parent form is nondimensionalized before geometric variations are made.

The planing hull form is approximated by straight line segments as shown in Figure 1. The general arrangements used for conventional planing hulls and landing craft are shown in Figures 2 and 3, respectively.

IMAT

Control for hull structural material 6

IMAT = 1 for aluminum hull
IMAT = 2 for steel hull

IMAT = 4 for GRP single skin hull,
 with sandwich plate bulkheads*

IMAT = 5 for GRP sandwich plate hull
 with sandwich plate bulkheads*

^{*} GRP is glass reinforced plastic, i.e., fiberglass.

TIMEC	Portion of time operating at cruise speed		33-40
FUELR	Cost of fuel per ton in dollars		41-48
	Note: TIMED + TIMEC = 1.0		
DELDT	<pre>Increment of displacement in tons for optimization routine if IOPT = 3</pre>	28	1-8
DELBX	Increment of max beam $B_{\mbox{\scriptsize PX}}$ in ft for		9-16
	optimization routine if IOPT > 1		
DELHD	Increment of hull depth H_h in ft for		17-24
	optimization routine if IOPT > 0		
BXMIN	Minimum value of $B_{ extsf{PX}}$ in ft		25-32
	If not restricted, make BXMIN = 0		
BXMAX	Maximum value of $\mathtt{B}_{ extsf{PX}}$ in ft		33-40
	If not restricted, make BXMAX very large		
HDMIN	Minimum value of ${\tt H}_{\!h}$ in ft		41-48
	If not restricted, make $HDMIN = 0$		
HDMAX	Maximum value of ${\tt H}_{\tt h}$ in ft		49-56
	If not restricted, make HDMAX very large		
PL	Ship projected chine length $L_{\overline{p}}$ in ft	29	1-8
DTONS	Initial value of displacement $\boldsymbol{\Delta}_{LT}$ in long tons		9-16
врх	Initial value of beam $B_{ m PX}$ in ft		17-24
HDM	Initial value of hull depth H_h in ft		25-32
A1=RWF(1)	Bare hull R/W at design speed		3 3- 40
A2=RWF(2)	Bare hull R/W at cruise speed		41-48
A3=FVOLSS	Volume of superstructure in ft^3		49-56

Card Set 29 is actually read by the main routine PHFMOPT, but is included here for convenience. One card is read for each hull variation desired. Blank card is inserted at end to terminate program.

^{*} Optional parameters to supersede corresponding values on Cards 7 and 11.

CONSTANTS:	Set by DATA statements
RHO	Water density ρ in 1b × sec ² /ft ⁴ $\rho = 1.9905$ for sea water at 59 F
VIS	Kinematic viscosity of water \vee in ft 2 /sec
	$v = 1.2817 \times 10^{-5}$ for sea water at 59 F
GA	Acceleration of gravity g in ft/sec ² g = 32.174 at 45 deg north latitude
RHO2	ρ/2
RG	Density in $1b/ft^3 = \rho g$
TON	Pounds per ton = 2240
DPR	Multiplier to convert degrees to radians = 57.29578
RPD	Multiplier to convert radians to degrees = 0.01745329
ZERO	0.0
HALF	1./2.
TWO	2.0
FOUR	4.0
EIGHT	8.0
TWELVE	12.0
THIRD	1./3.
THIRD2	2./3.
NL	6 = dimension of arrays for loads
N1	14 = dimension of arrays for structures, Group 1
N2	10 = dimension of arrays for propulsion, Group 2
N3	6 = dimension of arrays for electric plant, Group 3
N4	4 = dimension of arrays for communication and control, Group 4
N5	<pre>21 = dimension of arrays for auxiliary systems, Group 5</pre>
N6	<pre>17 = dimension of arrays for outfit and furnishings, Group 6</pre>
	First item in each array is total for the group. Last item in each array, except loads, is the margin. Intermediate Items are BSCI 3-digit groupings.

LO	Array of numerical identification for loads
L1 L2	
L2	Arrays of numerical identification for items in
1.3	Groups 1, 2, 3, 4, 5, 6 respectively, corresponding
L4	to BSCI codes in most cases. The margins are arbitrarily appended with 99.
L5	divictatily appended with 199.
16

		_	H _h

NAME:

SUBROUTINE CREWSS

PURPOSE:

Define ship's complement if not specified on input

cards

Define superstructure dimensions

CALLING SEQUENCE:

CALL CREWSS

INPUT:

Via COMMON blocks

DTONS

 $\Delta_{I,T}$ = ship displacement in long tons, from PHFMOPT

PL

 L_p = ship length in ft, from input Card 29

ACC

Total accommodations -- optional input on Card 10

CREW

Number of enlisted men--optional input on Card 10

CPO

Number of CPO's--optional input on Card 10

OFF

Number of officers--optional input on Card 10

FVOLSS

Volume of superstructure in ft³--optional input on

Card 11

OUTPUT:

Via COMMON blocks

= total ship weight in long tons = $\Delta_{L,T}$

DMULT

= multiplier for items which vary with ship size

= $[\ln (W+90)-2.55]/4.92$ for W < 2000

= 1.0 for W > 2000

NACCM

Number of personnel concerned with military payload

NACCM = 0.052 W

if W < 100

NACCM = 0.012 W + 4

if W > 100 Number of personnel for operation of ship = 0.035W + 4

NACCS

ACC

Total accommodations = NACCM + NACCS, rounded up unless ACC has been specified on Card 10

CREW

Number of enlisted men = $5/7 \times ACC$ unless CREW has

been specified on Card 10

CPO

Number of CPO's = $1/7 \times ACC$ unless CREW has been

specified on Card 10

OFF

Number of officers = $1/7 \times ACC$ unless CREW has been

specified on Card 10

Note: CPO and/or OFF can be set to 0 by input card if CREW is specified greater than 0. However, if CREW is set to 0 or blank space left on input card, then CREW, CPO, and OFF are calculated from above

equations.

SUBROUTINE CREWSS

VOLSS	∇ = volume enclosed by superstructure in ft ³
	If input value of FVOLSS > 0, then ∇ = FVOLSS Otherwise, ∇ = 70 × W × M Δ
HSS	H = height of superstructure in ft = 8.0 initially

Subscripts are BSCI 3-digit code The superstructure, foundations for propulsion and other equipment, and attachment are calculated in Subroutine TOTALS.

NAME:

SUBROUTINE STRUCT (to be used when ILC=0 and IMAT>2)

PURPOSE:

Calculate weights, volumes, and VCG's of major structures, Group 1, for planing hulls of glass reinforced plastic (GRP)

CALLING SEQUENCE:

CALL STRUCT

INPUT:

Via COMMON blocks

IMAT

Control for type of construction, from input

Card 6

IMAT

IMAT = 3 for GRP single skin, with single

skin bulkheads = 4 for GRP single skin, with sandwich

plate bulkheads

IFRM

Control type of framing

IFRM = 1 for transverse framing
IFRM = 2 for longitudinal framing

WSFMIN

S_{min} = minimum unit weight of plating in lb/ft,² from Card 11; 2.5 lb/ft² for sandwich

plate; 3.25 lb/ft^2 for single skin

WSLOPE

Sp = slope of unit weight curves for bottom
 plating as function of design load,
 from Card 11

STRESS

 σ_{limit} = stress limit in lb/in², from Card 11

DMAT

 γ_{mat} = density of material in 1b/ft³, from Card 11

Other

Hull geometry for subroutines NEWHULL, NEWVOL, etc. Via COMMON blocks

OUTPUT:

A. GENERAL

PRES

= design pressure on plating in 1b/in²

UNITWT

S = unit weight of plating in lb/ft^2

Curves of unit weight for GRP single skin and sandwich plate are shown in Figures 4 and 5.

B. PLATFORM DECKS

NPL

 $n_{pl} = 0$ if H_h is 10 ft or less

 $n_{p1} = 1$ if H_h is between 10 and 20 ft

 $n_{p1} = 2$ if H_h is 20 ft or greater

SUBROUTINE STRUCT (to be used when ILC=1 and IMAT<3) NAME:

PURPOSE: Calculate weight, volumes, and VCG's of major

structures, Group 1, for <u>landing craft</u> with well

CALLING SEQUENCE: CALL STRUCT

Via COMMON blocks INPUT:

> IMAT = 1,2 for structures of aluminum or steel, IMAT

from Card 11

= minimum unit weight of plating in lb/ft². WSFMIN Smin

= slope of unit weight curves, from Card 11 WSLOPE $S_{\mathbf{p}}$

= density of structural material in lb/ft³, DMAT

from Card 11

Lwell = length of well deck in ft, excluding aft XLWELL

ramp, from Card 6A

= length of bow ramp in ft, from Card 6A **XLBOWR**

 B_{well} = breadth of well deck in ft, from Card 6A **BWELL**

BBOWR B_{bow} = breadth of bow ramp in ft, from Card 6A

BAFTR Baft = breadth of aft (drive through) ramp in ft,

from Card 6A

Zwell = height of well deck above baseline in ft, **ZWELL**

from Card 6A

ZAFTR = height of aft ramp above baseline in ft,

from Card 6A

Hull geometry from Subroutines NEWHUL, NEWVOL, etc. Other

OUTPUT: Via COMMON blocks

GENERAL EQUATIONS

Same as Subroutine STRUCT for conventional planing

NAME:

SUBROUTINE POWER

PURPOSE:

Estimate power requirements at design and cruise speeds. Calculate weights, volumes, and VCG's of major components of propulsion system, Group 2. Calculate fuel required for range specifications.

CALLING SEQUENCE:

CALL POWER

SUBROUTINES CALLED:

PHRES, PRCOEF, SAVIT, PROPS, WJETS

INPUT:

Via COMMON blocks

VDES

V_d = design (maximum) speed in knots, from input Card 7

VCRS

 V_c = cruise speed in knots $\leq V_d$, from Card 7

RANGED

Range d = range requirement at design speed in

nautical miles, from Card 7

May be 0 if cruise range dominates

RANGEC

H13D

H13C

 $^{\text{H}}_{1/3}_{d}$ = maximum significant wave height in ft specified for operation of ship at $^{\text{V}}_{d}$, from Card 7

 $H_{1/3}$ = maximum significant wave height in ft specified for operation of ship at V_c ,

from Card 7

IPROP

Control for type of thrusters, from Card 6

IPROP = 1 for Gawn-Burrill type propellers

IPROP = 2 for Newton-Rader type propellers

IPROP = 3 for Wageningen B-screw type propellers

IPROP = 4 for wateriet pumps

IPM

Control for type of engines, from Card 6
IPM = 1 for diesel prime movers

IPM = 2 for gas turbine prime movers

IPM = 3 for CODOG system
IPM = 4 for COGOG system

DLBS

 Δ = ship displacement in 1b, from Subroutine NEWHUL

PRN

AUXNO

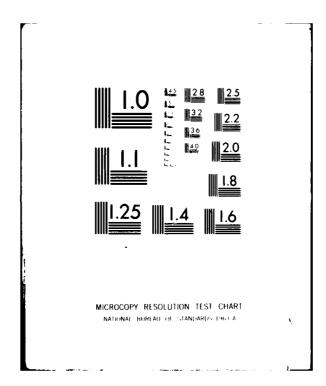

n = number of auxiliary engines, from Card 12

Other

Various constants relating to engines and gears

from input Cards 13, 14, and 15

Volumes of items not specified are assumed to be negligible.

Weights and volumes from these general equations for the outfit and furnishings will be multiplied by appropriate K-factors input on Cards 24 and 25. These multiplications and summations of all Group 6 weights are performed in Subroutine TOTALS.

NAME:	SUBROUTINE LOADS
PURPOSE:	Calculate weights, volumes, and VCG's of the fuel load, crew and effects, personnel stores, and potable water
CALLING SEQUENCE:	CALL LOADS
INPUT:	Via COMMON blocks
WF	W _F = weight of fuel in tons to meet range requirement(s), from Subroutine POWER
HDM	H_h = hull depth at midships in ft, from PHFMOPT
ACC	<pre>acc = total accommodations, from Card 10 or Sub- routine CREWSS</pre>
DAYS	days = number of days for provisions, from Card 10
XL array	K-factors for the loads, from card 16
OUTPUT:	Via COMMON blocks
WL(2)	W_{F} = weight of fuel in tons
ZL(2)	Z_F = VCG of fuel / hull depth, see Figure 2
	Z_F = centroid of midship section C_{S_m}/H_h if $H_h \le 10.0$
	$Z_F = (H_h - 8.0)/H_h \text{if } 10.0 < H_h \le 20.0$
	$Z_F = (H_h - 16.0)/H_h \text{ if } H_h > 20.0$
VL(2)	$\nabla_{\mathbf{F}}$ = volume of fuel in ft ³ = 42.96 × W _F × 1.05
WL(3)	W_{L1} = weight of crew and personnel effects in tons = 0.120 × acc
ZL(3)	Z_{L1} = VCG of crew and effects / hull depth = 0.732
VL(3)	∇_{Ll} = volume of crew and effects in ft ³ = 0.344 × acc
WL(4)	W_{L6} = weight of personnel stores in tons = 0.00284 × acc × days
ZL(4)	Z_{L6} = VCG of personnel stores / hull depth = 0.536
VL(4)	∇_{L6} = volume of personnel stores in ft ³
	= $(1.05 \times acc \times days) + (0.265 \times acc^{1/2} \times days)$
	+ $(4.38 \times acc^{1/2} \times days^{1/2})$ + $(0.4 \times days)$ + 8.0
WL(5)	W_{L12} = weight of potable water in tons = 0.1485 × acc (40 gal per man)
ZL(5)	Z_{L12} = VCG of potable water / hull depth = 0.138

SUBROUTINE LOADS

VL(5)	$\nabla_{\rm L12}$ = volume of potable water in ft ³ = 5.35 × acc Weights and volumes of loads from the preceding general equations are multiplied by appropriate K- factors input on Card 16. Normally the K values are 1.0. VCG's are not affected by the multipliers.
WCE	W_{CE} = total weight of crew and provisions in tons = W_{L1} + W_{L6} + W_{L12}
ZCE	z_{CE} = net VCG of crew and provisions / hull depth = $(W_{L1}^{Z}_{L1} + W_{L6}^{Z}_{L6} + W_{L12}^{Z}_{L12})$ /
VCE	$\nabla_{\text{L1}} + \nabla_{\text{L6}} + \nabla_{\text{L12}}$ $\nabla_{\text{CE}} = \text{volume of crew and provision in ft}^{3}$ $= \nabla_{\text{L1}} + \nabla_{\text{L6}} + \nabla_{\text{L12}}$

NAME:	SUBROUTINE TOTALS
PURPOSE:	Calculate remaining weights for Groups 1 through 6 and apply multipliers from input Cards 17 through 25. Calculate margins and totals for each weight group. Calculate weight, volume, and VCG of the resultant useful load and the payload.
CALLING SEQUENCE:	CALL TOTALS
INPUT:	Via COMMON blocks

NAME:	SUBROUTINE COSTS
PURPOSE:	Estimate base cost of ship by major weight groups. Also estimate life costs of ship
CALLING SEQUENCE:	CALL COSTS
INPUT:	Via COMMON blocks
CKN array	Cost factors for weight Groups 1 through 6 and pay- load input on Card 26
OPHRS	Operating hours per month, from input Card 27
OPYRS	Total vehicle operating years, from Card 27
XUNITS	Number of vehicles to be built, from Card 27
TIMED	Portion of time operating at maximum speed, from Card 27
TIMEC	Portion of time operating at cruise speed, from Card 27
FUELR	Cost of fuel in dollars per ton, from Card 27
OUTPUT:	Via COMMON blocks
C(1)	C ₁ = cost of structures
C(2)	C ₂ = cost of propulsion
C(3)	C ₃ = cost of electric plant
C(4)	C ₄ = cost of non-military communication and control
C(5)	C ₅ = cost of auxiliary systems
C(6)	C ₆ = cost of outfit and furnishings
C(7)	$c_7 = cost of empty ship = c_1 + c_2 + c_3 + c_4 + c_5 + c_6$
C(8)	C ₈ = cost of payload
C(9)	C_9 = base cost of first unit = $C_7 + C_8$
C(10)	C ₁₀ = average cost of XUNITS
C(11)	C ₁₁ = life cost of personnel pay and allowances
C(12)	C ₁₂ = life cost of maintenance
C(13)	C ₁₃ = life cost of operations, except energy
C(14)	C ₁₄ = life cost of major support
C(15)	C ₁₅ = life cost of fuel
C(16)	C_{16} = total life cost = C_{10} + C_{11} + C_{12} + C_{13} + C_{14} + C_{15} Cost estimates are in millions of FY 77 dollars.

SUBROUTINE COSTS

The cost equations used are based on statistics developed under the ANCVE project and are not for public release.

Cost data from this program should be used only for comparative purposes, i.e., percentage change from some parent configuration, and not as absolute cost figures.

SUBROUTINE PHRES

PURPOSE:

Estimate the bare-hull, smooth-water resistance of a hard-chine planing hull from synthesis of Series

62 and 65 experimental data

CALLING SEQUENCE:

CALL PHRES (DLBS, FNV, SLR, DCF, SDF, RLBS)

SUBPROGRAMS CALLED:

DISCOT, YINTX, ClDSF

INPUT:

DLBS

 Δ = ship displacement in 1b

FNV

 $F_{n\nabla}$ = speed-displacement coefficient $V/(g\nabla^{1/3})^{1/2}$

SLR

 $L_{\rm p}/\nabla^{1/3}$ = slenderness ratio

DCF

 C_{Λ} = correlation allowance; may be 0

SDF

Standard deviation factor

SDF = 0.0 corresponds to mean resistance-weight R/W

curves derived from Series 62 and 65 data SDF = 1.645 corresponds to minimum R/W curves SDF can be used to approximate the resistance

curves for a particular hull form

OUTPUT:

RLBS

R, = bare-hull, smooth-water resistance in 1b

= \triangle (mean R/W - SDF \times σ)

 σ = standard deviation of Series 62-65 data

from mean R/W

PROCEDURE:

XFNV array

Tabulated values of $\mathbf{F}_{\mathbf{n}\vec{V}}$ from 0.0 to 4.0

ZSLR array

Tabulated values of $L_p/\nabla^{1/3}$ from 4.0 to 10.0

YRWM matrix

Tabulated values of mean R/W as f(F $_{\rm n}\nabla$, L $_{\rm p}/\nabla^{1/3}$)

for 100,000-lb planing craft derived from Series 62 and 65 experimental data. See Table 1 and Figure 9

YWSR matrix

Tabulated values of mean wetted area coefficients

 $S/\nabla^{2/3}$ from Series 62 and 65 hulls. See Table 2

and Figure 10

SD array

Tabulated values of standard deviation σ as $f(F_{n\nabla})$

See Table 1 and Figure 9

RWM

R/W for 100,000-1b planing craft interpolated from YRWM matrix of mean R/W values at input $F_{n\nabla}$ and

 $L_{p}/\nabla^{1/3}$

SUBROUTINE PHRES

WSR	$S/V^{2/3}$ and L_p/V	interpolated from YWSR matrix at input $\mathbf{F}_{\mathbf{n}\nabla}^{-1/3}$
	Subrout	ine DISCOT used for the double interpolation
SDM	σ inter	polated from SD array at input ${ t F}_{{ t n} abla}$
	Function	n YINTX used for single interpolation
RWM	(R/W) _m :	= corrected R/W for 100,000-1b planing craft = (mean R/W interpolated) - (SDF \times σ interpolated)
DLBM	∆ _m =	= displacement of 100,000-1b planing craft
XL		= linear ratio of actual ship to 100,000-1b craft
	=	$= (\Delta/\Delta_{\rm m})^{1/3}$
VFPSM	m =	= speed of 100,000-1b craft in ft/sec = 19.32 (input $F_{n\nabla}$)
VFPSS	V _s =	= speed of actual ship in ft/sec = $V_m \lambda^{1/2}$
PLM	m	= length of 100,000-lb craft in ft
	-	= 11.6014 (input $L_p/\nabla^{1/3}$)
PLS	L _s =	= length of actual ship in ft = L_{m} λ
REM		= Reynolds number of 100,000-1b craft = V L /v m
RES	"s	= Reynolds number of actual ship = $V_s L_s/v_s$
CFM	c _{Fm} =	Schoenherr frictional resistance coefficient for 100,000-1b craft
CFS	c _F s	Schoenherr frictional resistance coefficient for actual ship
		n ClDSF used to obtain Schoenherr frictional nee coefficients
SM		= wetted area of 100,000-1b craft in ft ² = 134.5925 S/ $\nabla^{2/3}$
SS	S _s =	• wetted area of actual ship in $ft^2 = S_m \lambda^2$
RM	R _m	resistance of 100,000-1b craft in 1b $(R/W)_{\mathfrak{m}} \stackrel{\triangle}{_{\mathfrak{m}}}$

SUBROUTINE PHRES

CTM			total resistance coefficient of 100,000-1b craft
			$R_{\rm m}/(V_{\rm m}^2 S_{\rm m} \rho_{\rm m}/2)$
CR	c _R	=	residual resistance coefficient = $C_{T_m} - C_{F_m}$
CTS	C _{Ts}	=	total resistance coefficient of actual ship $C_{\begin{subarray}{c} F \ s \end{subarray}} + C_{\begin{subarray}{c} A \end{subarray}} + C_{\begin{subarray}{c} A \end{subarray}}$
RLBS			resistance of actual ship in 1b $c_{T_s}^{\ \ v_s}^{\ \ 2} s_s^{\ \ \rho_s/2}$
VIS	ν _s	=	kinematic viscosity for actual ship, input via COMMON
VISM	ν _m	=	kinematic viscosity for tabulated data = 1.2817×10^{-5}
RHO2	0 /2	_	
RHU2	s'2	-	1/2 water density for actual ship, input via COMMON
RHO2M	ρ /2	=	1/2 water density for tabulated data = 1.9905/2

RMT	ΣM = sum of moments about CG in ft-1b = $P_T e_p + (D_F + D_S) f_F + D_W f_W$ Iterate with small changes in τ until $\Sigma M \le 0.001 \Delta$
NT	Number of iterations required to obtain equilibrium trim; maximum of 15 iterations
R	R_b = total horizontal resistance force in lb = D_T cos τ + P_T sin τ

SUBROUTINE PRCOEF

PURPOSE:

Estimate propulsion coefficients for planing hull

with propellers on inclined shafts

CALLING SEQUENCE:

CALL PRCOEF (FNV, TDF, ADF, TWF)

SUBPROGRAMS CALLED:

MINP, YINTE

INPUT:

FNV

 $F_{n\nabla}$ = speed-displacement coefficient = $V/(g\nabla^{1/3})^{1/2}$

OUTPUT:

TDF

1-t = thrust deduction factor

= total horizontal resistance of appendaged hull

/ total shaft-line thrust

ADF

= appendage drag factor

= resistance of bare hull / resistance of

appendaged hull

TWF

1-w = thrust wake factor = torque wake factor

REFERENCE:

Blount, D.L. and D.L. Fox, "Small Craft Power Predictions," Western Gulf Section of the Society

of Naval Architects and Marine Engineers (Feb 1975)

PROCEDURE:

1-t, 1-w, and $\boldsymbol{\eta}_{\boldsymbol{a}}$ interpolated from following table

of values at input value of $F_{n\nabla}$. The tabulated

data represent mean values from a bandwidth of data collected for numerous twin-screw planing craft and

reported in the above reference.

FV array $F_{ny} = 0.5$ 2.0 2.5 3.0 1.0 1.5 3.5 4.0 TDF $1-t = 0.92 \quad 0.92$ 0.92 0.92 0.92 0.92 0.92 0.92 TW array $1-w = 1.05 \quad 1.06$ 1.04 0.99 0.97 0.975 0.98 0.975 $n_a = 0.951 \quad 0.948 \quad 0.942 \quad 0.934$ AD array 0.925 0.913 0.900 0.885

SUBROUTINE OWKTQ

PURPOSE:

Calculate propeller open-water characteristics as function of pitch ratio, expanded area ratio, and number of blades from coefficients derived from

Wageningen B-Screw Series for airfoil section propellers

or modified coefficients for flat face, segmental

section propellers.

REFERENCE:

Oosterveld and Van Oossanan, "Recent Development in Marine Propeller Hydrodynamcis," Proceedings of the Netherlands Ship Model Basin 40th Anniversary (1972) and "Further Computer Analyzed Data of the Wageningen B-Screw Series," International Shipbuilding Progress,

Vol. 22 (July 1975).

CALLING SEQUENCE:

CALL OWKTQ

J

INPUT:

IPROP

Control for type of propellers

= 1 for Gawn-Burrill type

(flat face, segmental sections)

= 3 for Wageningen B-Screw type

(airfoil sections)

PD

P/D = propeller pitch/diameter ratio (0,6 to 1.6)

EAR

= propeller expanded area ratio (0.5 to 1.1) EAR

Z

= number of propeller blades (3 to 7)

OUTPUT:

N

= number of J values generated -- max of 60 \mathbf{n}_{T}

JΤ

= array of propeller advance coefficients in ascending order from (J=0) to (J at $K_{\mathbf{T}} \approx 0$)

in increments of 0.025 if P/D<1.2in increments of 0,050 if P/D>1.2

KT

= array of open-water thrust coefficients

= f(P/D, EAR, Z, J)

KQ

= array of open-water torque coefficients KQ

= f(P/D, EAR, Z, J)

 $\mathbf{K}_{\mathbf{T}}$ and $\mathbf{K}_{\mathbf{O}}$ developed from equation in above references for airfoil section propellers. For Gawn-Burrill type propellers (IPROP=1) the equations are modified to produce slightly higher $K_{\overline{T}}$ and $K_{\overline{0}}$ than B-Screw Series.

SUBROUTINE CAVKTQ

PURPOSE:

Calculate propeller characteristics in cavitation regime as function of pitch ratio, expanded area

ratio and cavitation number.

REFERENCE:

Blount and Fox, "Design Considerations for

Propellers in a Cavitating Environment," Marine

Technology (Apr 1978)

CALLING SEQUENCE: CALL CAVKTQ

SUBPROGRAMS CALLED: TQMAX

INPUT:

IPROP	Control	for type of propellers = 1 for Gawn-Burrill type (flat face, segmental sections) = 2 for Newton-Rader types = 3 for Wageningen B-Screw (airfoil sections)
PD	P/D	= propeller pitch/diameter ratio
EAR	EAR	= propeller expanded area ratio

```

SUBROUTINE CAVKTQ

MAXIMUM THRUST AND TORQUE LOADS:

Blount and Fox (see reference) give equations for maximum thrust and torque load coefficients in a cavitating environment based on regression of experimental data for the three propeller series used herein.

τ _{cm}	= maximum thrust load coefficient = a σ _{0.7R} b (transition region) = τ _{c_x} (fully cavitating region)
Q _{cm}	= maximum torque load coefficient = c o _{0.7R} d (transition region) = Q _{c_x} (fully cavitating region)

OUTPUT:		:	IPROP
T1	а а а	= 1.2 = 0.703 + 0.25 P/D = 1.27	1 2 3
T2	b b b	= 1.0 = 0.65 + 0.1 P/D = 1.0	1 2 3
Q1	c c	= 0.200 P/D = 0.240 P/D - 0.12 = 0.247 P/D - 0.0167	1 2 3
Q2	d d d	= 0.70 + 0.31 EAR ^{0.9} = 0.50 + 0.165 P/D = 1.04	1 2 3
TCX	${{\tau_{\mathbf{c}_{\mathbf{x}}}}\atop{{\tau_{\mathbf{c}_{\mathbf{x}}}}\atop{\tau_{\mathbf{c}_{\mathbf{x}}}}}}$	= 0.0725 P/D - 0.0340 EAR = 0.0833 P/D - 0.0142 EAR = 0.0	1 2 3
QCX	$Q_{\mathbf{c}_{\mathbf{X}}}$	= $[0.0185 (P/D)^2 - 0.0166 P/D + 0.00594]$ /EAR1/3	1
	$\mathbf{Q_{c_X}}$	= 0.0335 P/D - 0.024 EAR ^{1/2} = 0.0	2
RMAX	k	= 0.8	

Since full-scale trial data (see Figures 5 and 6 of reference) indicates actual thrust and torque in the transition region less than the maximums derived from the propeller series data, the factor k is applied to $\tau_{\rm C_m}$ and $Q_{\rm C_m}$ in the transition region. The factor k is not applied to $\tau_{\rm C_X}$ and $Q_{\rm C_X}$.

SUBROUTINE CAVKTQ

FUNCTION TOMAX

PURPOSE:

Calculate maximum thrust or torque coefficient in a cavitating environment as function of cavitation

number and advance coefficient

CALLING SEQUENCE: X = TQMAX (SIGMA, JT, ITQ)

INPUT:

SIGMA

= cavitation number

JT

= advance coefficient

ITQ

= 1 if maximum thrust coefficient required = 2 if maximum torque coefficient required

Variables: a, b, c, d, τ_{c_X} , Q_{c_X} , k, $1/2 A_p/D^2$

generated by Subroutine CAVKTQ

OUTPUT:

TQMAX

 $\mathbf{K}_{T_{\overline{\mathbf{m}}}}$ or $\mathbf{K}_{Q_{\overline{\mathbf{m}}}}$ depending on value of i

= maximum thrust load coefficient = $k = \sigma_{0.7R}^{b}$, or $\tau_{c_{x}}$ if greater

= τ_{c_m} (1/2 Ap/D²) (J²+4.84) K_{T_m}

= maximum torque load coefficient = $\mathbf{k} \ \mathbf{c} \ \sigma_{\mathbf{0.7R}}^{\mathbf{d}}$, or $\mathbf{Q_{C_X}}$ if greater

= Q_{c_m} (1/2 A_p/D^2) ($J^2+4.84$) $K_{Q_{\overline{m}}}$

SUBROUTINE PRINTP

PURPOSE:

Interpolate for propeller performance at specified value of (1) advance coefficient J, (2) thrust loading K_T/J^2 , (3) torque loading, K_0/J^2 , or

(4) power loading K_0/J^3 .

CALLING SEQUENCE: CALL PRINTP (IP, PCOEF, SIGMA)

NAME: SUBROUTINE DISCOT

PURPOSE: Single or double interpolation for continuous or

discontinuous function using Lagrange's formula

CALLING SEQUENCE: CALL DISCOT (XA, ZA, TABX, TABY, TABZ, NC, NY, NZ,

ANS)

SUBPROGRAMS CALLED: UNS, DISSER, LAGRAN

These subroutines are concerned with the interpo-

lation, and are not documented separately

INPUT:

XA x value (first independent variable) for interpolated

point

ZA z value (second independent variable) for interpolated

point

Same as x value for single-line function interpolation

TABX array Table of x values--first independent variable

TABY array Table of y values--dependent variable

TABZ array Table of z values--second independent variable

NC Three digit control integer with + sign

Use + sign if NX = NY/NZ = points in X array

Use - sign if NX = NY

Use 1 in hundreds position for no extrapolation

above maximum Z

Use 0 in hundreds position for extrapolation

above maximum Z

Use 1-7 in tens position for degree of interpolation

desired in X direction

Use 1-7 in units position for degree of interpolation

desired in Z direction

NY Number of points in y array

NZ Number of points in z array

OUTPUT:

ANS

y value (dependent variable) interpolated at x, z

DISCOT is a "standard" routine used at DTNSRDC. Consult User Services Branch of the Computation, Mathematics and Logistics Department for additional

information.

FUNCTION MINP

PURPOSE:

Select index of minimum x value to be used for Lagrange interpolation, from an array of x values

greater than required

CALLING SEQUENCE:

I = MINP (M, N, XA, X)

INPUT:

M

m = number of points required for interpolation of

degree m-1

N

n = total number of points in x array > m

XΑ

x value to be used for interpolation

X array

Table of x values, must be in ascending order, but

need not be equally spaced

OUTPUT:

MINP

Index of minimum x value from the array to be used by

FUNCTION YINTE for Lagrange interpolation of

degree m-1

SAMPLE PROGRAM USING FUNCTIONS MINP AND YINTE:

DIMENSION X(10), Y(10)

N = 10

M = 4

READ (5, 10) (X(J), J=1, N), (Y(J), J=1, N), XA

I = MINP (M, N, XA, X)

YA = YINTE(XA, X(1), Y(1), M)

ALTERNATE PROGRAM USING FUNCTION YINTX:

DIMENSION X(10), Y(10)

N = 10

M = 4

READ (5, 10) (X(J), J=1, N), (Y(J), J=1, N), XA

YA = YINTX (XA, X, Y, M, N)

The result from either program is the same. In either case, only the M points closest to XA are considered in the interpolation formula. The first combination should be used whenever several dependent variables are to be interpolated at some value of the independent variable, since MINP need only be called once. FUNCTION YINTE may be used alone whenever N = M.

FUNCTION YINTE

PURPOSE:

Single interpolation of degree n-1 for function represented by n (x,y) points using Lagrange's

formula

CALLING SEQUENCE:

YA = YINTE(XA, X, Y, N)

INPUT:

XA

x value (independent variable) for interpolated point

X array

Table of x values--independent variable

x values can be in either ascending or descending

order and do not need to be equally spaced

Y array

Table of y values--dependent variable

N

n = number of (x,y) values defining the function

OUTPUT:

YINTE

Interpolated y value (dependent variable) derived

from Lagrange formula of degree n-1

For example, when n = 4, cubic interpolation is

performed

Lagrange's Interpolation Formula

$$y = \frac{(x-x_1) (x-x_2) \dots (x-x_n)}{(x_0-x_1) (x_0-x_2) \dots (x_0-x_n)} y_0$$

$$+ \frac{(x-x_0) (x-x_2) \dots (x-x_n)}{(x_1-x_0) (x_1-x_2) \dots (x_1-x_n)} y_1$$

$$+ \frac{(x-x_0) (x-x_1) (x-x_3) \dots (x-x_n)}{(x_2-x_0) (x_2-x_1) (x_2-x_3) \dots (x_2-x_n)} y_2 + \dots$$

$$+ \frac{(x-x_0) (x-x_1) (x-x_2) \dots (x-x_n)}{(x_n-x_0) (x_n-x_1) (x_n-x_2) \dots (x_n-x_{n-1})} y_n$$

FUNCTION YINTX

PURPOSE:

Single interpolation of degree m-1 for function represented by n (x,y) points using Lagrange's formula. If n > m, only the m closest points are

considered in the interpolation formula

CALLING SEQUENCE:

YA = YINTX (XA, X, Y, M, N)

INPUT:

XΑ

x value (independent variable) for interpolated point

X array

Table of x values--independent variable x values must be in ascending order, but need not be equally spaced

Y array

Table of y values--dependent variable

M

m = number of (x,y) values considered for the

interpolation process of degree m-1

N

 $n = total number of (x,y) values \ge m$

OUTPUT:

YINTX

Interpolated y value (dependent variable) derived

from Lagrange formula of degree m-1

FUNCTION YINTX may be used instead of FUNCTION MINP

and FUNCTION YINTE together

See Sample Programs using these three functions

FUNCTION SIMPUN

PURPOSE:

Numerical integration of area under curve defined by

set of (x,y) points at either equal or unequal

intervals

CALLING SEQUENCE: AREA = SIMPUN (X, Y, N)

INPUT:

X array

Table of x values--independent variable

x values must be in ascending order

Y array

Table of y values--dependent variable

N

Number of (x,y) values

OUTPUT:

SIMPUN

Area under curve ≈ ∫y dx

NAME:

FUNCTION C1DSF

PURPOSE:

Calculate Schoenherr frictional resistance coefficient

CALLING SEQUENCE: CF

= C1DSF (XN1RE)

INPUT:

XN1RE

Reynolds number = V L / v

OUTPUT:

C1DSF

Schoenherr frictional resistance coefficient

PROCEDURE:

Iteration with Newton-Raphson method

Schoenherr formula: $0.242 / \sqrt{C_F} = \log_{10} R_n C_F$

LIBRARY SUBPROGRAMS:

Example

ABS	a	= absolute value of a	B = ABS (A)
AMINI	Min(a, b,)	= smallest value in list	C = AMIN1 (A,B)
ALOG	log (a)	= natural logarithm of a	D = ALOG (A)
ALOG10	log ₁₀ (a)	= common logarithm of a	E = ALOG10 (A)
ATAN	arctan(a)	= arctangent of a	F = ATAN (A)
	arctan(a/b)	= arctangent of a/b	G = ATAN (A,B)
cos	cos(a)	= trigonometric cosine of a	P = COS(A)
Ε/γP	e ^a	= exponential of a	Q = EXP (A)
SIN	sin(a)	= trigonometric sine of a	R = SIN (A)
SQRT	$(a)^{1/2}$	* square root of a	S = SQRT (A)
TAN	tan(a)	= trigonometric tangent of a	T = TAN (A)

Note: Angle A must be in radians for trigonometric functions SIN, COS, TAN

DTNSRDC ISSUES THREE TYPES OF REPORTS

- 1. DTNSRDC REPORTS, A FORMAL SERIES, CONTAIN INFORMATION OF PERMANENT TECHNICAL VALUE. THEY CARRY A CONSECUTIVE NUMERICAL IDENTIFICATION REGARDLESS OF THEIR CLASSIFICATION OR THE ORIGINATING DEPARTMENT.
- 2. DEPARTMENTAL REPORTS, A SEMIFORMAL SERIES, CONTAIN INFORMATION OF A PRELIMINARY, TEMPORARY, OR PROPRIETARY NATURE OR OF LIMITED INTEREST OR SIGNIFICANCE. THEY CARRY A DEPARTMENTAL ALPHANUMERICAL IDENTIFICATION.
- 3. TECHNICAL MEMORANDA, AN INFORMAL SERIES, CONTAIN TECHNICAL DOCUMENTATION OF LIMITED USE AND INTEREST. THEY ARE PRIMARILY WORKING PAPERS INTENDED FOR INTERNAL USE. THEY CARRY AN IDENTIFYING NUMBER WHICH INDICATES THEIR TYPE AND THE NUMERICAL CODE OF THE ORIGINATING DEPARTMENT. ANY DISTRIBUTION OUTSIDE DTNSRDC MUST BE APPROVED BY THE HEAD OF THE ORIGINATING DEPARTMENT ON A CASE-BY-CASE BASIS.
